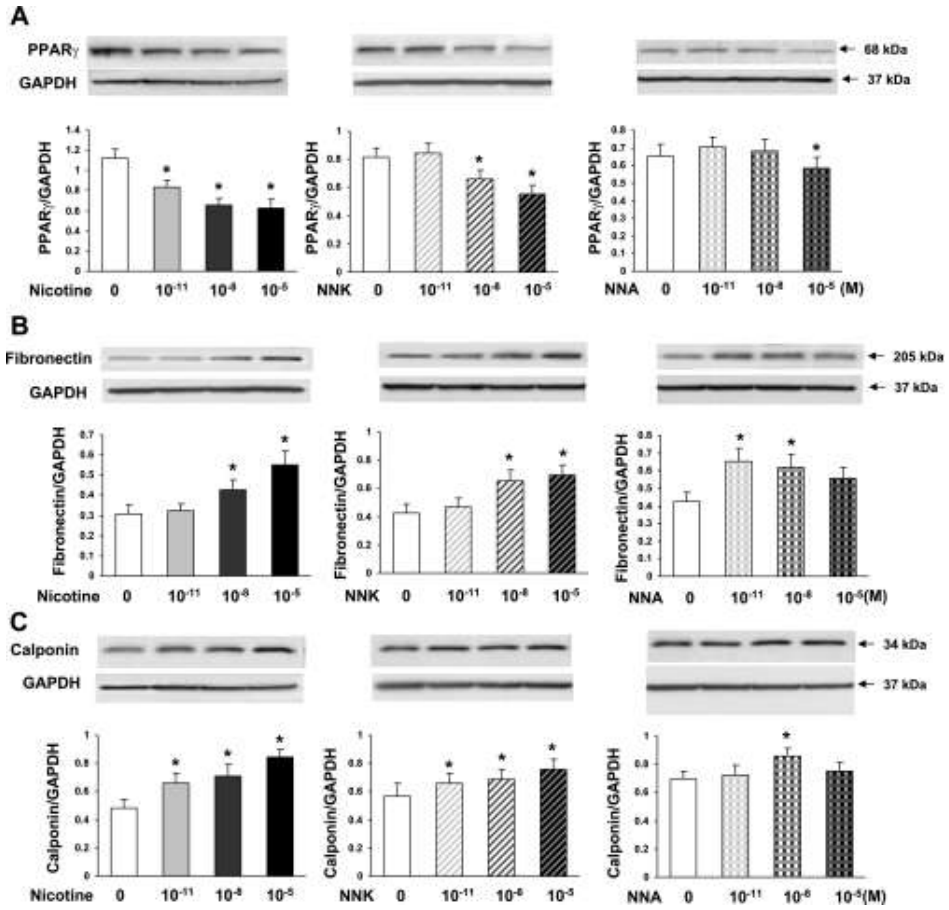
1. Effect of age at the time of CS exposure
2. Effect of CS on lungs
3. Pathogenesis of smoking related interstitial lung disorders

5026 BC

1560 France

Ad 1. Effect of age at the time of CS exposure

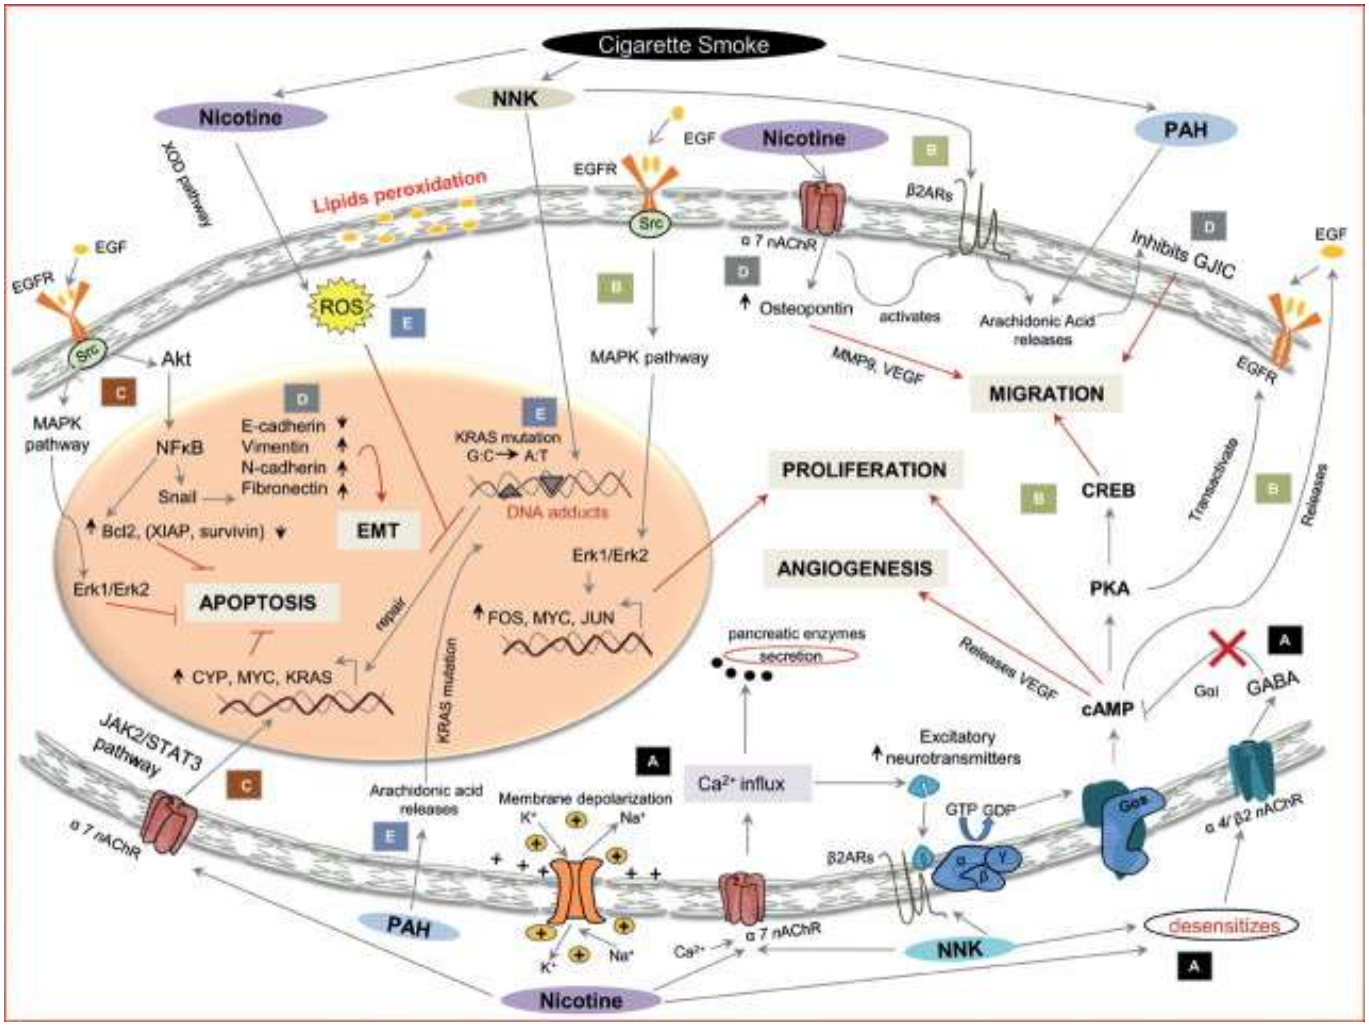


-Third hand smoke - genome instability and faster telomere shortening
-Methylation and downregulation of miRNA (placenta, cord blood, peripheral blood)

-Second hand smoke - higher concentrations of benzol(a)pyrene, toluene, nitrosamines, smaller particles more likely to be deposited in the lung
-Exposure to carcinogens during periods of rapid cell division – genetic abnormalities – lung cancer, fibrogenesis

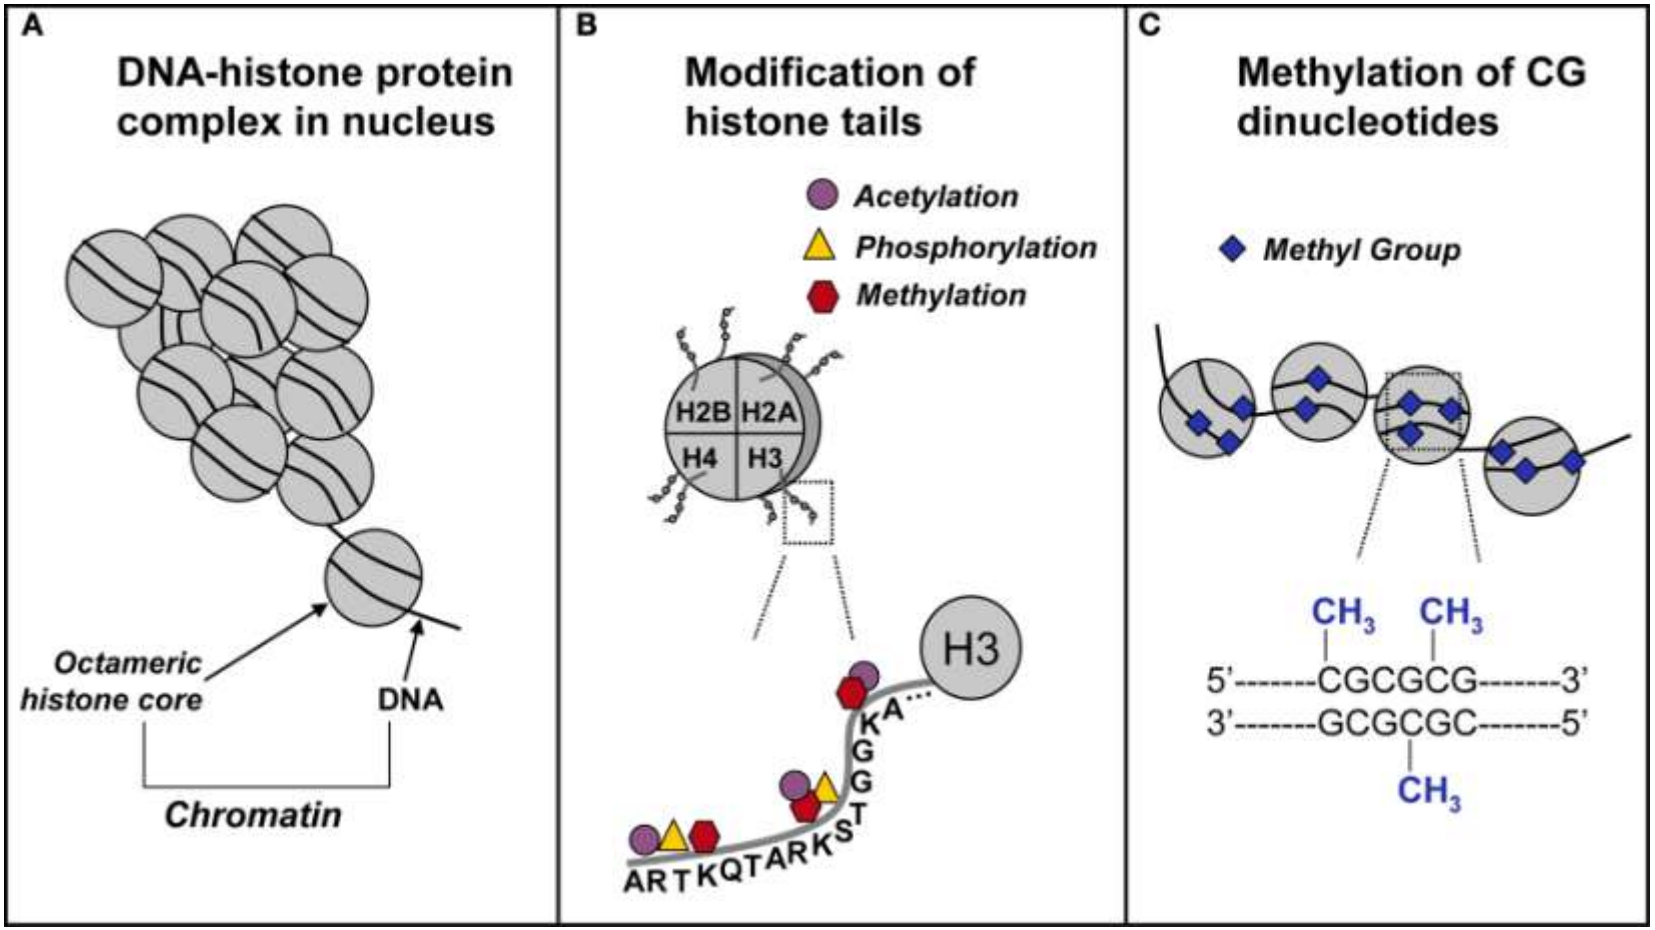
Rehan VK, et al. Am J Physiol Lung Cell Mol Physiol 2011 ;31:L1-L8.

Ad 2. Effect of CS on lung cells



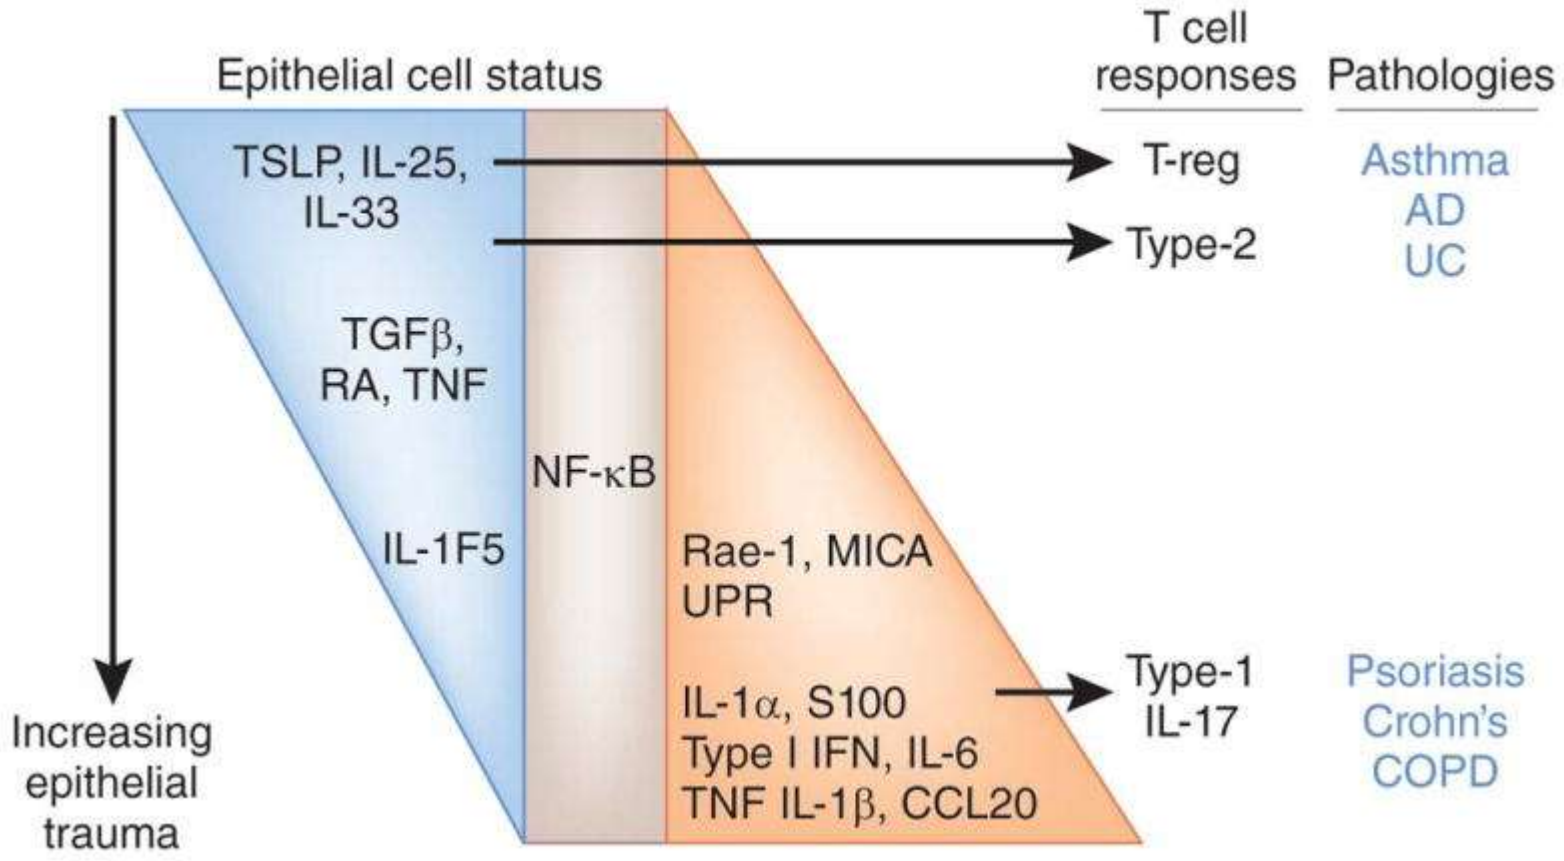
Momi N, et al. Carcinogenesis 2012; 33.1617-28.

Smoking-induced epigenetic events

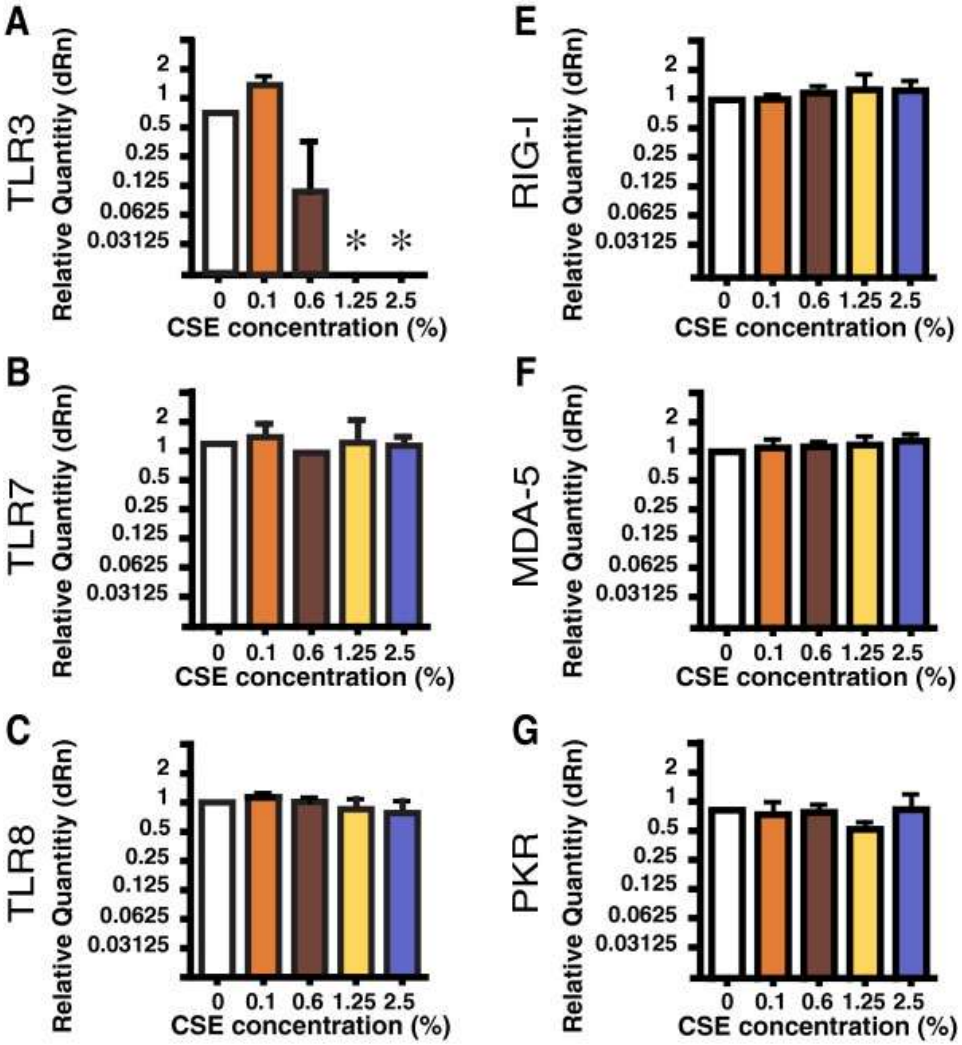


Penner MR, et al. Front Ag Neurosci 2010; 2:9.

Effect of cigarette smoke - epimmunome



Swamy M, et al. Nat Immunol 2010;11: 656–65.



Infection susceptibility

-CS favours colonisation by pathogens
-Enhances bacterial attachment to epithelial cells, promotes changes in virulence by modifying bacterial gene expression

- Reduction in lung Mø TLR3 expression may be one mechanism contributing to the increased incidence of viral respirator infections in smokers and to viral induction of acute exacerbations

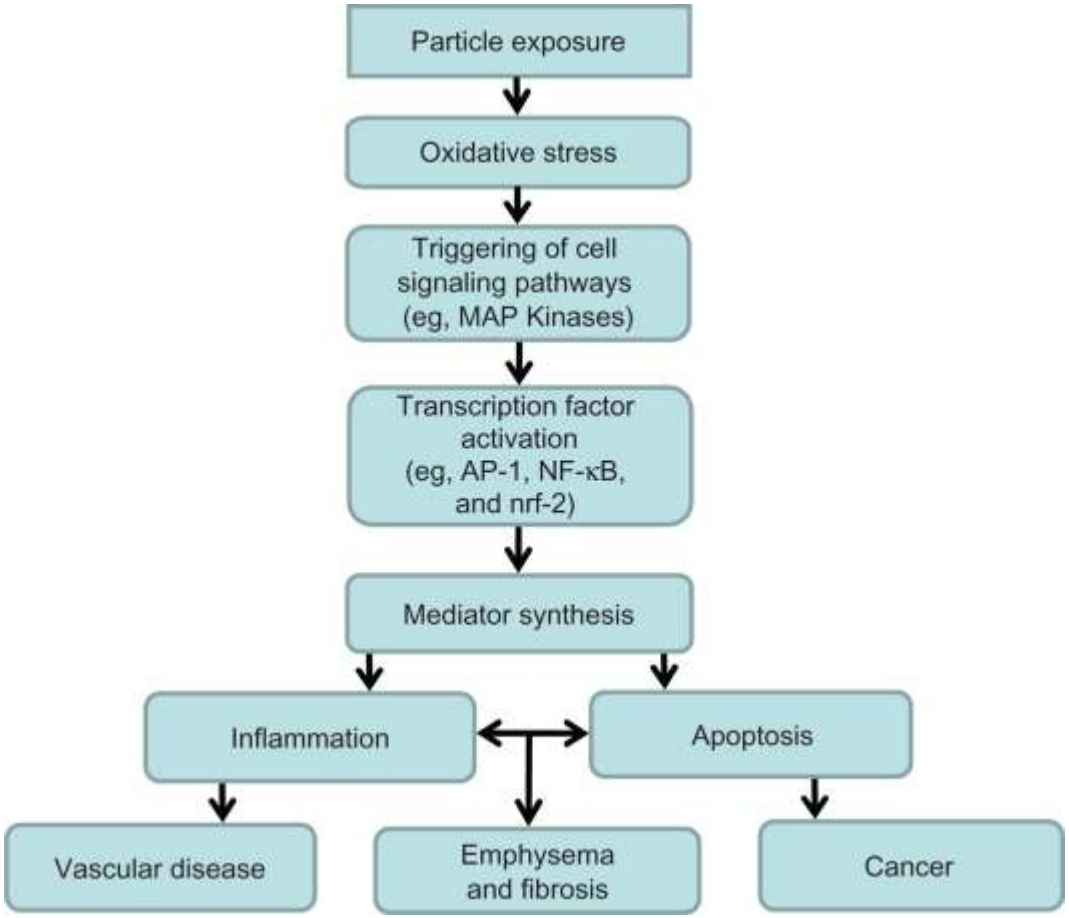
Todt JC, et al. Respir Res 2013; 14:33.
Garmendia J, et al. European Respiratory Journal 2012; 39:467-477.

Mechanisms of nicotine-induced fibrogenesis

- Promotes damage to epithelial/endothelial barriers
- Stimulates the production and release of TGF-β1
- Recruits inflammatory cells
- Activates ROS production
- Activates collagen-producing cells

Jensen K, et al. FASEB Journal 2012; 26:4778-4787.

Particle related effect of cigarette smoke



Sangani RG, et al. International Journal of COPD 2011; 6:191-198.

Modification of environmental exposures prevent/delay onset of short telomere syndrome

Table 4. Relationship between smoking, fibrogenic exposures and pulmonary fibrosis in *TERT* mutation carriers ≥40 years of age.

Exposure	No. of Subjects with Exposure	No. of Subjects without Exposure	P-Value*	Odds Ratio [95% confidence interval]
Smoking, present or past				
Pulmonary Fibrosis	20	8	0.02	4.0 [1.2, 14.5]
No Pulmonary Fibrosis	11	18		
Fibrogenic Exposure**				
Pulmonary Fibrosis	20	8	0.18	2.3 [0.7, 8.1]
No Pulmonary Fibrosis	15	14		
Smoking and/or Fibrogenic Exposure				
Pulmonary Fibrosis	27	1	0.005	13.6 [1.7, 636.8]
No Pulmonary Fibrosis	19	10		

*By Fisher's exact test.

**The self-reported fibrogenic exposures include ingestion of methotrexate and nitrofurantoin; exposure to birds and bird antigens including parakeets, cockatiels, and eagle feathers; occupational exposures to asbestos, welding, carpentry, mining, sandblasting, cement manufacturing, railroad work, insulation; and household exposure to water damage and significant mold.

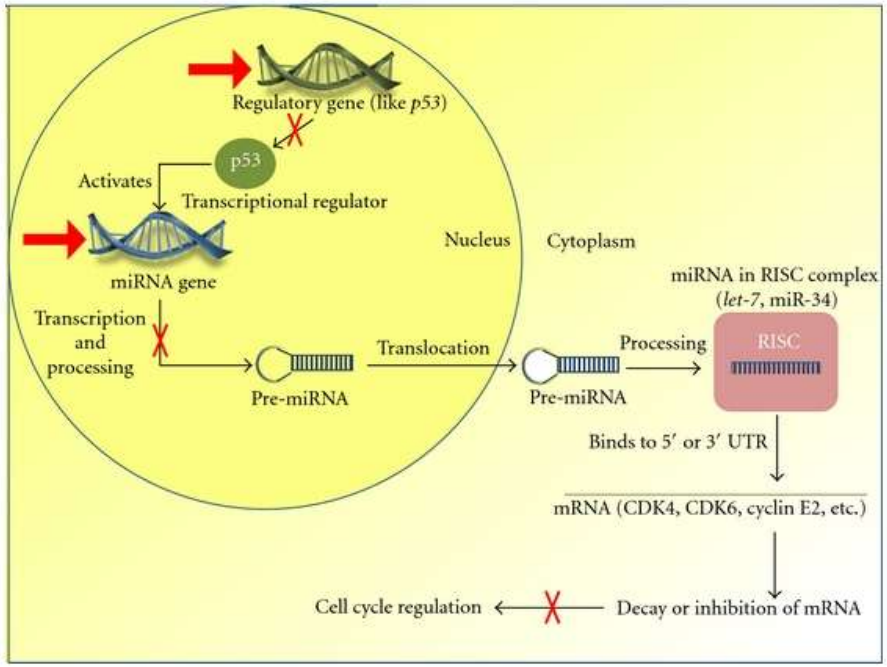
Cigarette smoke induced dysregulation of microRNA expression



-Repressors of genic expression at the posttrascriptional level, degrading messenger RNA or inhibiting its protein translation

-Correlation between smoke exposure-induced dysregulation of miRNAs and age
-Dysregulation intensity and duration associated
-Short term exposure-reversible changes, adaptive response mech
-Longer exposure-irreversibility of changes in expression

-Association among polymorphisms of genes for enzymes playing role in coping with reactive oxygen and nitric species in asbestosis patients

Franko A, et al. Biomed Res Int 2013; 2013:405743.

Smoking and ILD associated with organic/anorganic antigen exposure

- Protective effect of CS on the development of hypersensitivity pneumonitis
- Long-term exposure to PDE without CS: ↑ in lung weight/body weight ratio, total cell number in bronchoalveolar lavage (BAL) fluid, and content of hydroxyproline in the lung compared to short term exposure
- Short-term exposure to PDE+CS: ↓the lymphocytosis in BAL fluid, and lymphocyte proliferation
- Long-term exposure to PDE+CS: ↑ lung hydroxyproline.

IPF, idiopathic pulmonary fibrosis; rheumatoid arthritis-interstitial lung disease.

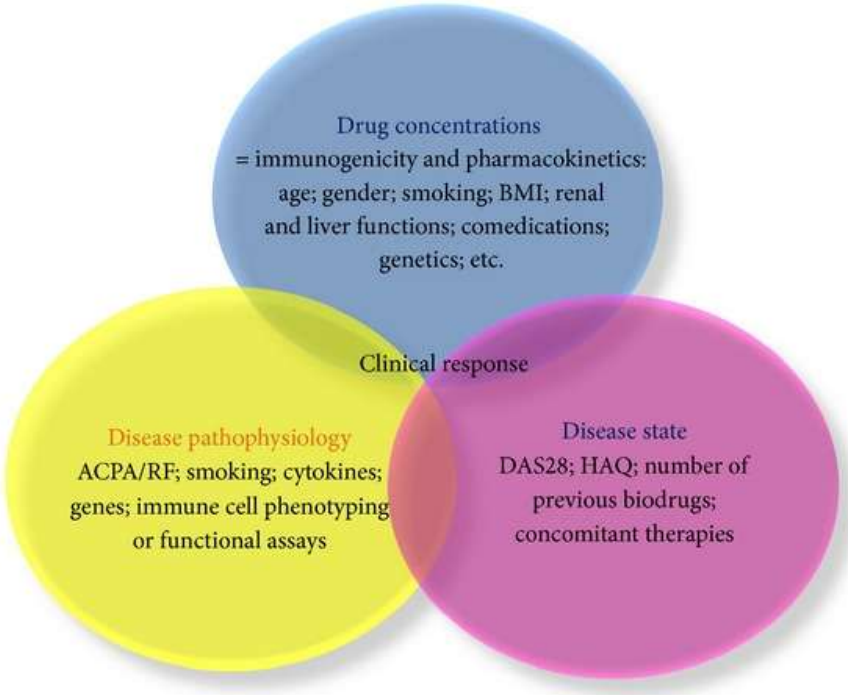
Antoniou KM, et al. Respirology 2013; 18:1191-6.

Smoking and rheumatoid arthritis

- Smoking associated with development of extraarticular manifestations and progressive disease course
- Promotes citrullination of synovial proteins
- Smoking + HLA shared epitopes alleles --- autoimmunity trigger
- ILD in RA males, >10 py UIP
- Lower PY – emphysema, prevalence 48% RA-ILD

Cavagna L, et al. Biomed Res Int 2013; 2013: 759760.

Smoking and rheumatoid arthritis treatment



-Lower infliximab response
-Limit efficiency of corticosteroids to attenuate the transcription of inflammmatory genes
-Induce cytochrome P450 activity

Daien CI, et al. Mediators Inflamm 2014; 2014: 386148.

Smoking and rheumatoid arthritis treatment

Table 2: Main predictive factors of response to biological therapy.

Factors associated with good response to	Tumor necrosis factor inhibitors	Tocilizumab	Abatacept	Rituximab
Patients characteristics	Male (C) [7–9] Younger (C) [7, 8] Nonsmoker (C) [10, 19–21] Nonobese for IFX (C) [16, 17] Use of MTX (C) [7, 8, 10, 11]	Older (NC) [12]	Younger (NC) [13]	Male (NC) [15]
Disease characteristics	Low HAQ (C) [7, 10, 17, 20] High DAS28 (C) [7, 8, 17] ACPA or RF negativity (C) [20, 31] Low number of previous biological therapies (C) [8]	Low HAQ and high DAS28 [13]	High DAS28 [14] RF positivity (C) [32]	Low HAQ and high DAS28 [15, 32] RF positivity +++ (C) [32] Low number of previous biological therapies (C) [29]
Immunogenicity	Antidrug antibodies against ADA or IFX for response to ETN (NC) [39]			
Genetic background	PTPRC = CD45 (rs10919563) (C) [41, 42], 7 SNPs including EYA4 (rs17301249) and PDZD2 (rs1532269) (NC) [43]			158VV FCGR3A in European countries (C) [44, 45]
Cytokines and immune cells	High TNF bioactivity in blood [5] or in synovium [49] (NC), high LPS-stimulated whole blood IL-1b (NC) [48], low IL-17 (NC) [6] 24-biomarker ETN response signature including autoantibodies and cytokines (C) [53]	High serum IL-6 levels (NC) [54]	Low levels of CD4+ and CD8+ CD28− T cells (NC) [61]	Memory B cells (NC) [57, 58]

C: confirmed; NC: not confirmed. To be confirmed, the data had to be validated at least by two independent teams.

MODERN PATHOLOGY (2012) 25, S68–S78

Smoking-related interstitial fibrosis (SRIF), pathogenesis and treatment of usual interstitial pneumonia (UIP), and transbronchial biopsy in UIP

Anna-Luise A Katzenstein

Department of Pathology, SUNY Upstate Medical University, Syracuse, NY, USA

This review focuses on three selected topics of current interest that are related to chronic fibrosing lung disorders and are important for pathologists. First, the clinical and pathologic features of smoking-related interstitial fibrosis (SRIF) are highlighted. SRIF is a common finding in smokers that has striking histologic changes but only mild associated clinical manifestations. It is characterized by marked alveolar septal fibrosis composed of a distinct form of hyalinized collagen deposition. The process is present mainly in subpleural and centrilobular parenchyma and is associated with emphysema and respiratory bronchiolitis. Second, important aspects of the pathogenesis and treatment of usual interstitial pneumonia (UIP) are reviewed. The current theory proposes that UIP is caused by tiny foci of acute lung injury (manifest pathologically by fibroblast foci) that occur and recur in the interstitium over many years. Inflammation may be present as a secondary phenomenon, but is not the primary cause, and therefore anti-inflammatory agents have little effect. The recurrent injury leads to permanent fibrosis, through a process that is considered to represent a form of abnormal wound healing. Multiple therapies have been attempted that are aimed largely at interrupting the fibrosing process, but none have been successful. The cause of the injury is unknown, but a role for aspiration due to gastroesophageal reflux is a popular current theory, and there is some evidence that anti-reflux therapy may be beneficial. Genetic predisposition has been implicated in the etiology of familial cases, and there is evidence that telomere shortening may be important in sporadic cases. Third, the use of transbronchial biopsy (TBB) in diagnosing UIP is reviewed. TBB can provide a surprising amount of information and is especially useful in certain situations, such as elderly or very sick patients in whom surgical lung biopsy carries increased morbidity and mortality.
Modern Pathology (2012) **25,** S68–S78; doi:10.1038/modpathol.2011.154

Keywords: interstitial fibrosis; pulmonary fibrosis; SRIF; TBB; transbronchial biopsy; UIP

Smoking related interstitial fibrosis

Table 2 Contrasting histologic features of SRIF, UIP, and fibrosing NSIP

SRIF	*UIP*	*Fibrosing NSIP*
Hyalinized, ropey, deeply eosinophilic collagen with no to minimal inflammation	Light staining collagen with minimal inflammation	Light staining collagen with admixed inflammation
Mainly subpleural, centrilobular	Random distribution	Relatively diffuse
Relatively uniform involvement	Heterogeneous, patchwork distribution[a]	Relatively uniform involvement
Emphysema, often severe	Emphysema usually absent	Emphysema usually absent
Respiratory bronchiolitis present	+/− Respiratory bronchiolitis	+/− Respiratory bronchiolitis
No/minimal honey-comb change	Honey-comb change present	No/minimal honey-comb change
No/rare fibroblast foci	Fibroblast foci present	No/rare fibroblast foci

[a]Patchwork distribution is defined as the apposition of abnormal areas and normal lung areas in a random pattern without any gradation or areas of transition between them. SRIF and NSIP lack this heterogeneous appearance, but they may be patchy. The difference is that SRIF and NSIP areas blend into the normal areas rather than being sharply demarcated without transition.
